Excerpt: .as the sum or as the difference of two prisms or cylinders each having one end perpendicular to the length. We infer that in all cases the volume is equal to the area of the cross-section multiplied by the distance between the mass-centres of the two ends. Ex. The volume of the wedge-shaped solid cut off from a right circular cylinder by a plane through the centre of the base, making an angle α with the plane of the base, is $\frac{4}{3} \pi r^2 \sin \alpha \tan \alpha = \frac{8}{3} r^2 \tan \alpha$; cf. Art. 114, Ex. 1. The theorems of Pappus may be generalized in various ways; but it may be sufficient here to state the following extension of the second theorem. If a plane area, constant or continuously variable, move about in any manner in space, but so that consecutive positions of the plane do not intersect within the area, the volume generated is equal to $\int S da$ (2), where S is the area, and da is the projection of an element of the locus of the mass-centre of the area on the normal to the plane. If ds denote an element of this locus, and θ the angle between ds and the normal to the plane, the formula may also be written $\int S \cos \theta ds$ (3). This theorem is the three-dimensional analogue of the proposition of Art. 101, relating to the area swept over by a moving line. It is a simple corollary from the...
